# Kooperative DNA Bindung

► **FIGURE 11-24 Cooperative binding of two unrelated transcription factors to neighboring sites in a composite control element.** By themselves, both monomeric NFAT and heterodimeric AP1 transcription factors have low affinity for their respective binding sites in the *IL-2* promoter-proximal region. Protein-protein interactions between NFAT and AP1 add to the overall stability of the NFAT-AP1-DNA complex, so that the two proteins bind to the composite site cooperatively. [See L. Chen et al., 1998, *Nature* **392**:42.]

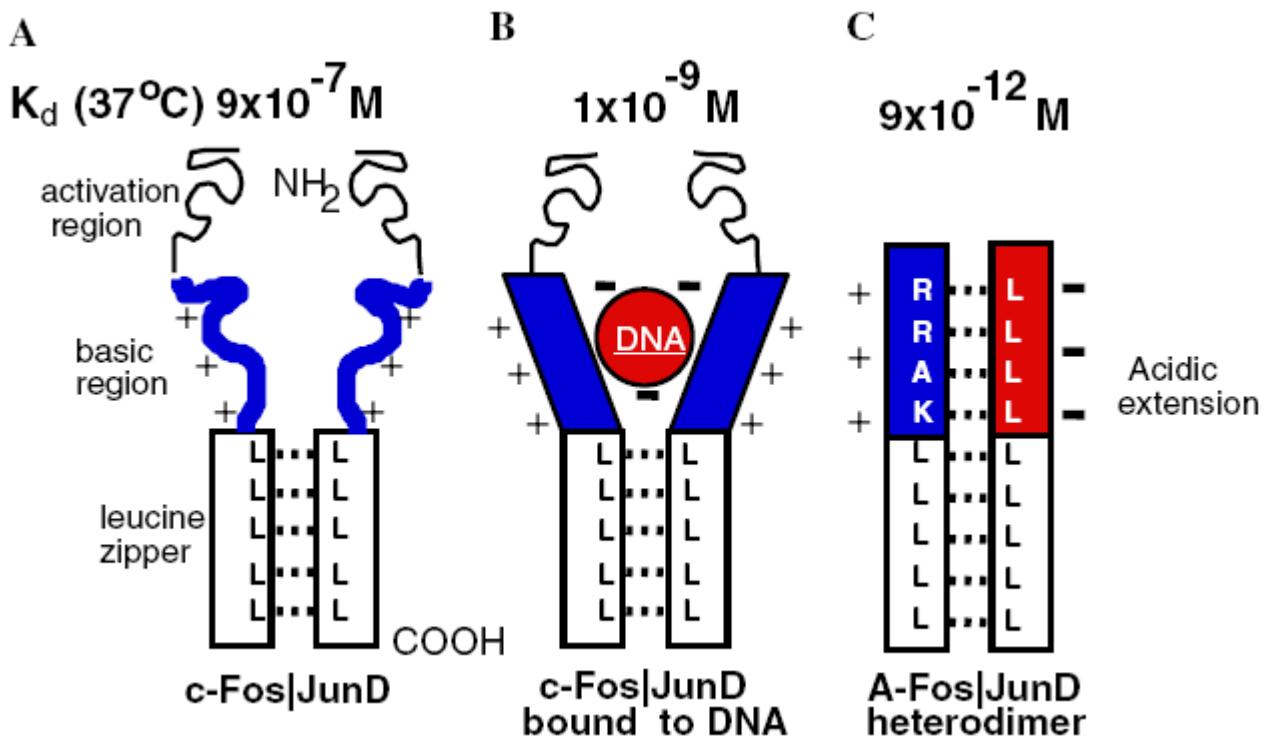

# Regulation erfordert komplexe Strukturen

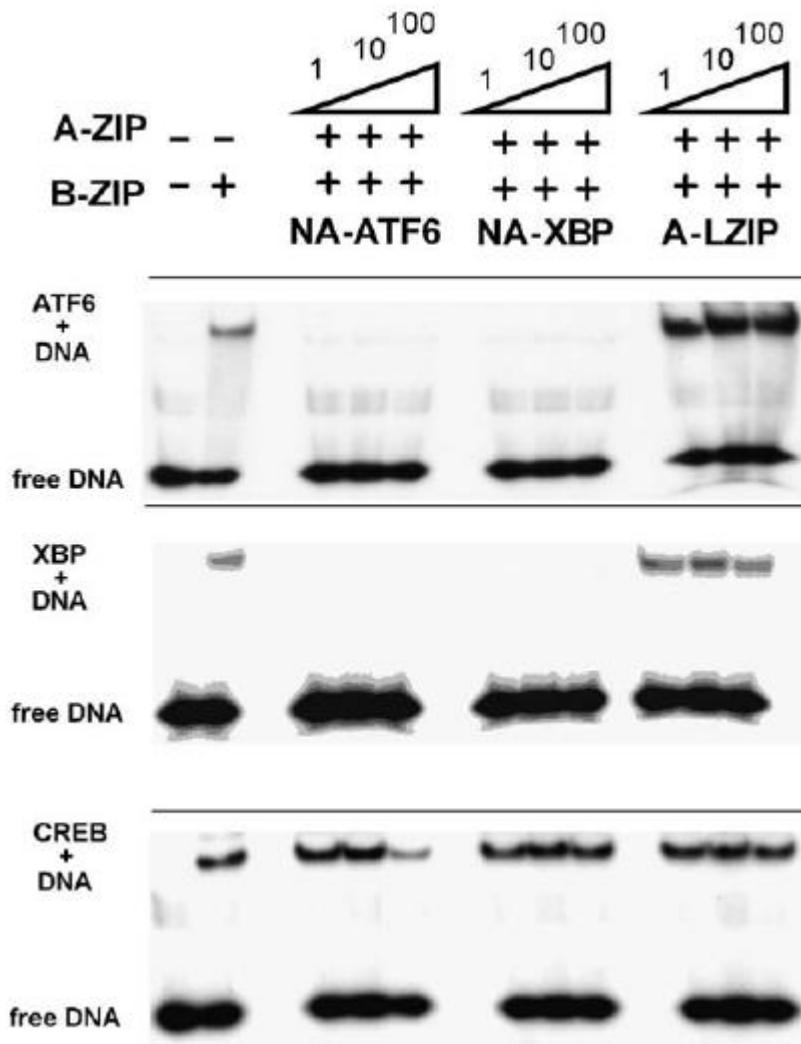

▲ **FIGURE 11-26 Model of the enhancesome that forms on the  $\beta$ -interferon enhancer.** Two monomeric transcription factors, IRF-3 and IRF-7, and two heterodimeric factors, Jun/ATF-2 and p50/ p65 (NF- $\kappa$ B) bind to the four control elements in this enhancer. Cooperative binding of these transcription factors is facilitated by HMGI, which binds to the minor groove of DNA and also interacts directly with the dimeric factors. Bending of the enhancer sequence resulting from HMGI binding is critical to formation of an enhancesome. Different DNA-bending proteins act similarly at other enhancers. [Adapted from D. Thanos and T. Maniatis, 1995, *Cell* **83**:1091, and M. A. Wathel et al., 1998, *Mol. Cell* **1**:507.]

# Zinc Finger

**FIGURE 28-31** Typical steroid hormone receptors.

These receptor proteins have a binding site for the hormone, a DNA-binding domain, and a region that activates transcription of the regulated gene. The highly conserved DNA-binding domain has two zinc fingers. The sequence shown here is that for the estrogen receptor, but the residues in bold type are common to all steroid hormone receptors.

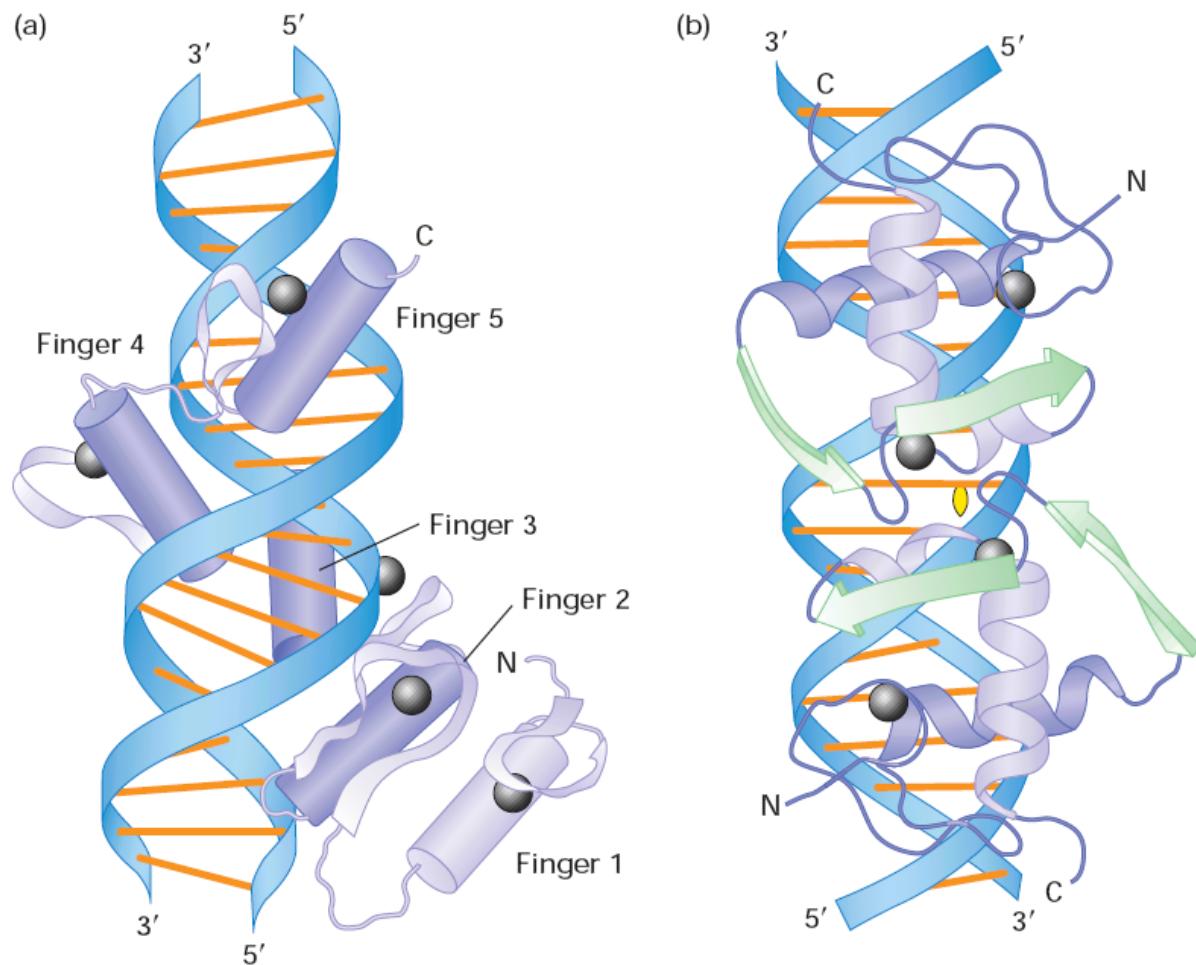

# Zinc Finger DNA Bindung

**FIGURE 28-12 Zinc fingers.** Three zinc fingers (gray) of the regulatory protein Zif268, complexed with DNA (blue and white) (PDB ID 1A1L). Each  $\text{Zn}^{2+}$  (maroon) coordinates with two His and two Cys residues (not shown).

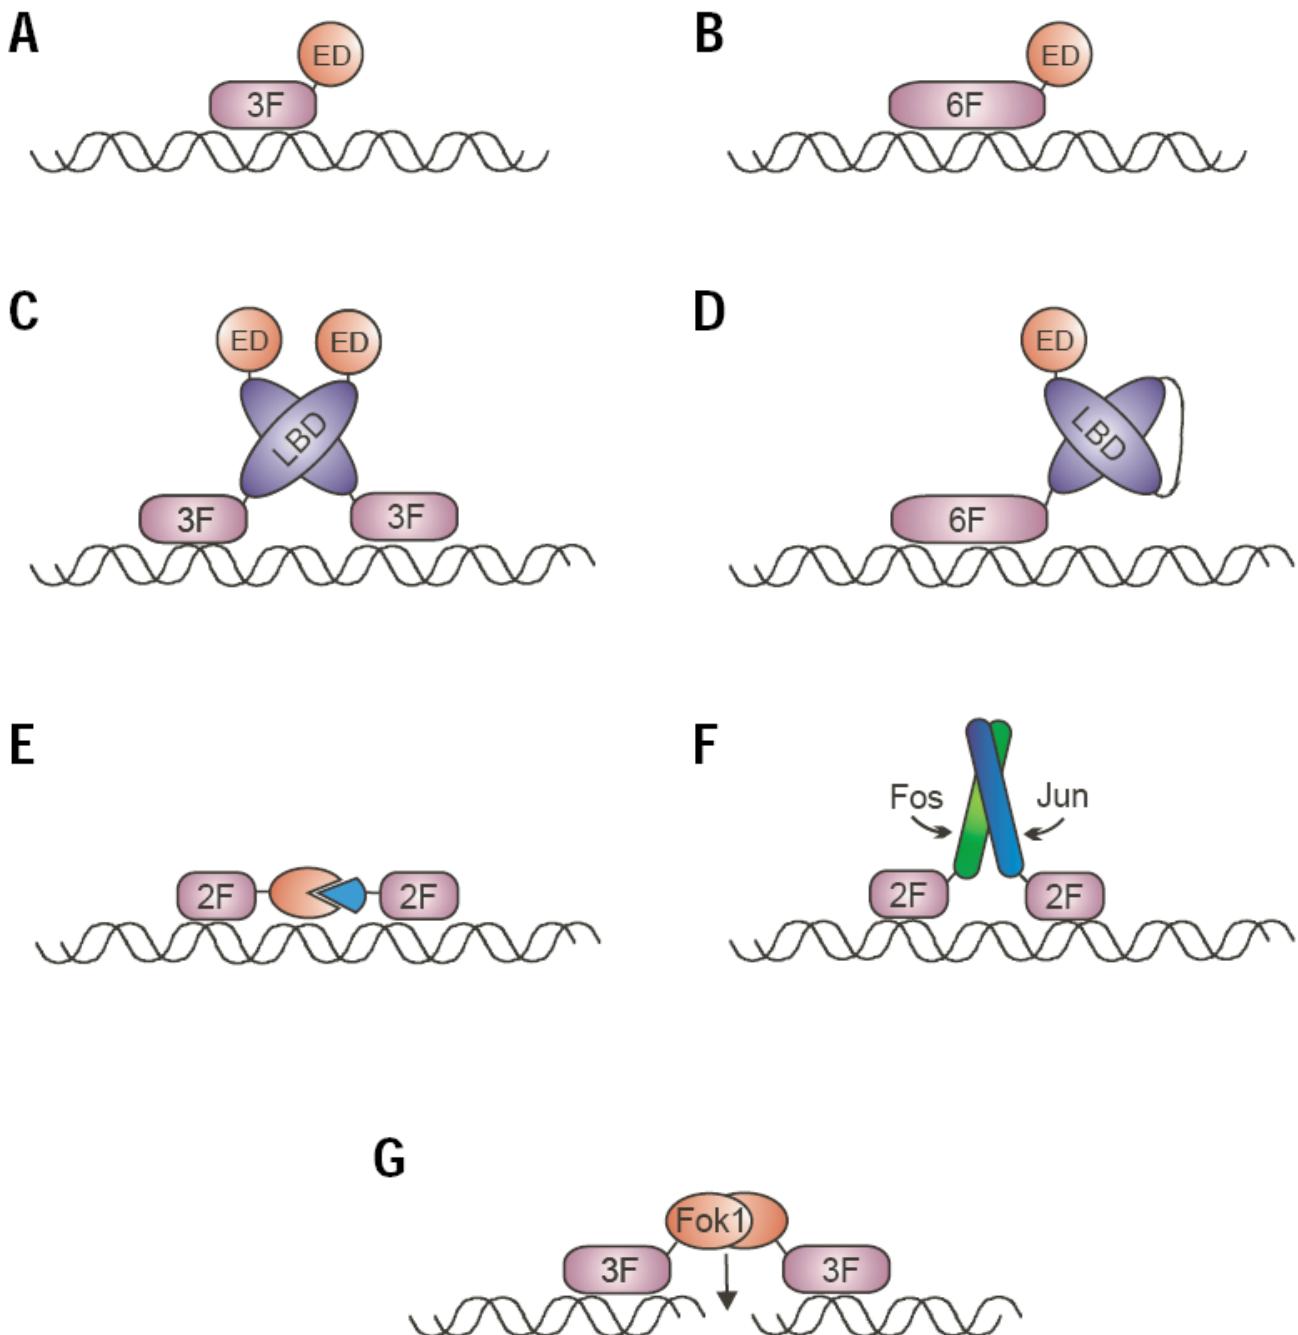

# Verknüpfung mehrerer Finger

► **FIGURE 11-21** Interaction between DNA and proteins containing zinc fingers.  
(a) GL1 is a monomeric protein that contains five  $\text{C}_{\text{2H}_2}$  zinc fingers.  $\alpha$ -Helices are shown as cylinders,  $\text{Zn}^{+2}$  ions as spheres. Finger 1 does not interact with DNA, whereas the other four fingers do. (b) The glucocorticoid receptor is a homodimeric  $\text{C}_4$  zinc-finger protein.  $\alpha$ -Helices are shown as purple ribbons,  $\beta$ -strands as green arrows,  $\text{Zn}^{+2}$  ions as spheres. Two  $\alpha$  helices (darker shade), one in each monomer, interact with the DNA. Like all  $\text{C}_4$  zinc-finger homodimers, this transcription factor has twofold rotational symmetry; the center of symmetry is shown by the yellow ellipse. In contrast, heterodimeric nuclear receptors do not exhibit rotational symmetry. [See N. P. Pavletich and C. O. Pabo, 1993, *Science* **261**:1701, and B. F. Luisi et al., 1991, *Nature* **352**:497.]
